Re.: Geotechnical Base Line Report
US 15 Bridge Replacement over Indian Field Swamp
Dorchester County, South Carolina
SCDOT Project ID P037127
F&ME File No. G6100.12

Mr. Harris:

Submitted herein is the geotechnical base line report for the above referenced project. Included is a summary of the subsurface investigation, the subsurface findings, the soil laboratory test results, and our preliminary evaluation for the conceptual bridge foundation systems and bridge/roadway embankments.

Please notify us if there are any questions or if we can be of further assistance.

Respectfully Submitted,

F&ME CONSULTANTS

John F. Hamilton, P.E.
Geotechnical Design Manager

Alex P. Ross, E.I.T.
Geotechnical Associate

1. PROJECT DESCRIPTION

The project is located approximately three (3) miles northeast of the Town of Saint George, South Carolina. A site location plan is presented in Section 1 of the Appendix.

We understand that the project consists of replacing the existing bridge over Indian Field Swamp with a new bridge structure. An existing box culvert may also be replaced as part of this project. We anticipate the proposed roadway grade will be less than five (5) feet relative to the centerline of the existing embankment. Embankment widenings will result in embankment side slopes extending over natural ground soils.

The geotechnical field investigation was performed by F&ME in general accordance with the SCDOT Geotechnical Design Manual and the SCDOT Scope of Services work order, dated July 17, 2019.

2. SUBSURFACE INVESTIGATION

From September 19-26, 2019, four (4) bridge soil test borings (designated as B-1 through B-4), five (5) cone penetrometer soundings (designated as CPT-1 through CPT-4, and CPT-3A), four (4) roadway embankment soil test borings (designated as R-1 through R-4), four (4) bulk soil samples (designated as BS-1 through BS-4), and two (2) multi-channel analysis of surface waves (MASW) tests were performed in the vicinity of the project.

The soil test borings were advanced utilizing a trailer-mounted CME 45B drill rig. The borings utilized rotary wash drilling techniques to maintain a stable borehole. Standard Penetration Tests (SPT) were continuously obtained in the top ten (10) feet of each test boring. Following the continuous sampling, SPT samples were obtained at regular, five (5) foot intervals throughout the remaining depths of the borings. SPT samples were performed in general accordance with ASTM D-1586 to determine the relative densities and consistencies of the subsurface soils and to collect subsurface soil samples. An automatic hammer was used to perform the SPTs. The measured energy ratio for the CME 45B hammer is 92%.

The bridge and roadway borings were advanced to target depths and were subsequently terminated. In general, the bridge and roadway borings extended to depths of 100 feet and thirty (30) feet below the top of the existing embankments, respectively. CPT soundings extended to a depth where the maximum reaction force of the rig was observed. In general, the CPT's extended to depths ranging from twenty (20) to thirty (30) feet below the top of the existing embankments.

Bulk soil samples were collected for laboratory testing to provide either soil strength parameters for the existing embankment soils or soil parameters for pavement subgrades. The bulk soil samples were collected and composited from an approximate depth of one (1) to five (5) feet below the existing ground surface.

The locations, depths, and elevations of the borings performed for the subsurface investigation are provided in the following table.

| Subsurface Investigation Summary Table | | | | | |
|--|------------------|--------------------|---------------------------|---------------------------------|-----------------------|
| Boring I.D. | Test Hole Locale | Station (US 15) | Offset from CL (ft) | Boring Elevation (ft-MSL) | Test Depth (ft) |
| B-1 | Bridge | 90+58 | 8'-RT | 78.8 | 100 |
| B-2 | Bridge | 91+29 | 8'-LT | 78.9 | 100 |
| B-3 | Bridge | 98+06 | 8'-RT | 79.9 | 100 |
| B-4 | Bridge | 98+86 | 6'-LT | 79.9 | 100 |
| R-1 | Road | 88+01 | 7'-RT | 79.7 | 30 |
| R-2 | Road | 93+00 | 8'-LT | 79.0 | 28.8 |
| R-3 | Road | 96+01 | 7'-RT | 79.5 | 30 |
| R-4 | Road | 102+01 | 7'-RT | 81.0 | 30 |
| CPT-1 | Bridge | 90+57 | 13'-LT | 78.4 | 28.25 |
| CPT-2 | Bridge | 91+29 | 13'-RT | 79.1 | 27.83 |
| CPT-3 | Bridge | 97+94 | 12'-LT | 79.4 | 18 |
| CPT-3A | Bridge | 97+79 | 12'-LT | 79.4 | 18.05 |
| CPT-4 | Bridge | 98+92 | 14'-RT | 78.2 | 18.58 |
| BS-1 | Bridge | 91+15 | 14'-LT | 78.1 | 5 |
| BS-2 | Road | 95+95 | 14'-RT | 78.9 | 5 |
| BS-3 | Bridge | 98+98 | 15'-RT | 80.2 | 5 |
| BS-4 | Road | 101+98 | 13'-RT | 81.6 | 5 |

The collected soil samples were examined and logged in the field by F&ME personnel, sealed in plastic bags, and transported to our laboratory for further examination and analyses. The soils were visually classified in the field based upon the Unified Soil Classification System.

We have provided a boring location plan in Section 3 of the Appendix displaying the locations of the borings performed during the subsurface investigation.

3. LABORATORY TESTING PROGRAM

Select soil samples from the borings were tested in F&ME's AASHTO certified laboratory to determine physical and engineering soil properties. These tests were used to identify the strength and behavioral characteristics of the soils as well as to verify the field classifications by the AASHTO classification system and the Unified Soil Classification System (USCS). The laboratory testing program is summarized in the following table.

Table 3.1 – Split-Spoon Laboratory Testing Summary Table

| Laboratory Soil Testing (Split-Spoon Samples) | | |
|---|----------|-----------------------------|
| Type of Test | Quantity | Procedure |
| Natural Moisture Content | 53 | AASHTO T265 (ASTM D2216) |
| Atterberg Limits | 53 | AASHTO T89/T90 (ASTM D4318) |
| Wash #200 | 45 | AASHTO T11 (ASTM D1140) |
| Grain Size Analysis with Hydrometer | 8 | ASTM D7928 |
| Organic Content | 2 | AASHTO T267 (ASTM D2974) |
| pH | 1 | AASHTO T289 (ASTM G51) |
| Resistivity | 1 | AASHTO T288 |
| Sulfate Content | 1 | AASHTO T290 (ASTM C1580) |
| Chloride Content | 1 | AASHTO T291 |

The laboratory testing performed for the bulk soil samples is detailed in the table below, and the data sheets containing the results are provided in the Appendix of this report.

Table 3.2 – Bulk Sample Laboratory Testing Summary Table

| Laboratory Soil Testing (Bulk Samples) | | |
|--|----------|-----------------------------|
| Type of Test | Quantity | Procedure |
| Natural Moisture Content | 4 | AASHTO T265 (ASTM D2216) |
| Atterberg Limits | 4 | AASHTO T89/T90 (ASTM D4318) |
| Grain Size Analysis with Wash #200 | 4 | AASHTO D6913 |
| Standard Proctor | 4 | AASHTO T99 (ASTM D698) |
| CBR | 2 | AASHTO T193 (ASTM D1883) |
| Direct Shear | 2 | AASHTO T236 (ASTM D3080) |
| pH | 1 | AASHTO T289 (ASTM G51) |
| Resistivity | 1 | AASHTO T288 |
| Sulfate Content | 1 | AASHTO T290 (ASTM C1580) |
| Chloride Content | 1 | AASHTO T291 |

All soil testing was conducted in general accordance with applicable ASTM/AASHTO standards. Data sheets presenting the results of the laboratory test program are provided in Section 9 of the Appendix.

4. GENERAL SITE GEOLOGY

The project site is located within the Middle Coastal Plain Physiographic Province of South Carolina. In descending order, the site subsurface conditions generally consist of existing embankment fill, Holocene-aged alluvium, oligocene-aged Ashley Formation soils, and eocene-aged Santee Limestone.

The Holocene-aged soils, of primarily alluvial origin, represent natural grade soils below the existing embankment fill material. The thickness of the Holocene soils ranged from approximately five (5) to ten (10) feet. The recovered samples within the Holocene layer were generally classified as loose, medium plasticity, clayey sands with fines contents between 20% and 40%.

Below the Holocene deposits, the encountered soils are consistent with the Oligocene-aged Ashley Formation (a member of the Cooper geologic group and formerly referred to as Cooper Marl). At this site, the Ashley Formation soils were generally classified as dark colored, non-plastic to low-plasticity silty sands or sandy silt. Typically, relative densities in the marl increase based on the age of the marl. The bridge site appears to be in an area of moderately-aged marl, and the observed SPT N-values are generally between ten (10) and twenty (20) blows per foot (bpf). These blow counts suggest medium dense sands and stiff to very stiff silts.

Underlying the Ashley Formation is the Santee Limestone. Silty and/or clayey calcareous sand was primarily identified in this formation. The identifying characteristic of this stratum is the “caprock” feature located at the top of the stratum. This feature is relatively thin (<1 ft thick) and may likely be a containment mechanism for the artesian water contained within the limestone. A majority of the stratum contained soils with appreciable calcium carbonate content. N-values typically ranged between twenty (20) and forty (40) bpf with interbedded thin, cemented layers having N-values of greater than 100 bpf. The Santee Limestone was encountered to a boring termination depth of 100 feet.

5. SUBSURFACE CONDITIONS

The below soil descriptions, strata depths, and consistencies are generalized and were interpreted by F&ME based on the subsurface conditions as encountered in the test borings. We have included the soil test boring logs in the Appendix for detailed descriptions of the encountered soil conditions. As with any geologic formation, the depth and thickness of the soil strata will vary across the site. Although the test borings designate strata changes at specific depths in the description of the soil stratigraphy on the soil test boring logs, transitions between soil strata are generally gradual. Therefore, the outlined subsurface profile shown on the soil test boring logs should only be considered general, on-site soil conditions and should not be utilized as an absolute indicator.

5.1 Soil Stratigraphy

The following table summarizes the soil stratification along the proposed roadway alignment.

| Soil Stratification Table | | | | | |
|---------------------------|------------------------------------|----------------------------|----------------|------------------------|---------------|
| Geologic Formation | Elevation of Top of Layer (ft-MSL) | Depth to Top of Layer (ft) | USCS Soil Type | Avg. SPT N-Value (bpf) | Comments |
| Existing Embankment Fill | +80 | 0 | SM/SC/SP-SM | 12 | Existing Fill |
| Alluvium | +74 | 6 | SM/SC | 6 | Holocene |
| Ashley Formation (Marl) | +68 | 12 | SM/ML | 15 | Oligocene |
| Santee Limestone | +51 | 29 | SC-SM/SM GP/SP | 36 | Eocene |

5.2 Subsurface Shear Wave Velocity

Geophysical testing consisting of two (2) Multi-channel Analysis of Surface Waves (MASW) tests were performed from the approximate top of the existing embankment areas, between the existing bridge and box culvert. The MASW array locations are provided on the Boring Location Plan in Section 3 of the Appendix. From the geophysical testing, two (2) subsurface shear wave velocity profiles were developed. Based on the shear wave velocity profile, the shear wave velocities begin to approximate 2,500 ft/sec at a depth of approximately forty (40) feet. The depth at which the subsurface shear wave velocity consistently exceeds 2,500 ft/sec is considered the B-C Boundary. Based on available geologic data and other deep boreholes in the general vicinity of the site, we do not believe that the B-C Boundary exists within the top 100 feet. We believe the limestone caprock and the cemented sand layers are dominating the shear wave velocity characteristics at the site. The graphical shear wave velocity profiles are provided in Section 7 of the Appendix.

The shear wave velocity information was submitted to SCDOT for development of the project seismic design data. The provided ADRS curves from the SCDOT are provided in Section 8 of the Appendix.

5.3 Groundwater Conditions

Groundwater table measurements were recorded immediately following completion of the borings and/or 24-hours following completion of the borings. The depth to the groundwater table ranged from approximately two (2) feet to ten (10) feet. These depths correspond to a groundwater elevation ranging from approximately +77 ft-MSL to +69 ft-MSL.

Groundwater elevations at this site will fluctuate with climactic events. During and following periods of rainfall, the water table may be encountered at higher elevations than identified on the field testing logs. During the field investigation, an artesian water condition was encountered in each of the deeper bridge borings. The artesian condition is believed to originate from the Santee Limestone formation. The artesian water pressure is believed to be contained by the caprock feature at the top of the limestone stratum. The observed water pressure head was approximately one (1) to four (4) feet above the water table measured at the time of boring. This may not be an accurate indicator of the artesian pressure as some of the artesian water may be moving laterally in the alluvial sands. No water was observed above the existing pavement elevations at the time of our field investigation. The Design-Build team should evaluate the groundwater conditions at the site and exercise engineering judgement when selecting foundation types.

6. CONCEPTUAL GEOTECHNICAL ASSESSMENT

The geotechnical information, provided herein, is conceptual and is based on limited geotechnical data. The information provided should be supplemented and evaluated relative to the SCDOT GDM and Team specific design and construction requirements for preliminary and final design purposes. Following the collection of additional subsurface data, these recommendations may change or become invalid. We have provided very general and conceptual geotechnical information based on the subsurface information collected by F&ME during this phase of the project.

6.1 Site Preparation

Based on the subsurface conditions encountered during the field investigation, the soil subgrades below the planned embankment areas appear to be adequate for embankment construction. The embankment subgrade soils are generally comprised of saturated, clay-like sands that may perform unsatisfactorily. At areas where new fill will be placed over these soils, localized mucking, bridge lifts, and/or soil reinforcement may be required to achieve acceptable performance. During and following periods of rainfall, mucking operations may be more prevalent.

6.2. Geotechnical Seismic Hazard Potential

Geotechnical seismic hazards consist of a loss in a soil's shear strength through cyclic ground motions induced by earthquakes. In sand-like soils, this phenomenon is typically referred to as soil liquefaction. Cyclic-softening is the typical terminology for fine grained soils. Liquefaction of sand-like soils is considered the most devastating seismically induced geotechnical hazard.

Liquefaction is the loss of a soil's shear strength due to a rapid increase in pore water pressure resulting from soil particle dilation induced by seismic vibrations. Soils most susceptible to liquefaction generally consist of saturated, loose, "clean" (i.e., Plasticity Indexes less than 7), fine (10% particle size ranging from 0.07 millimeters to 0.25 millimeters) sands. Soil softening occurs in moderate to high plasticity silts and clays.

Based on a qualitative review of the collected subsurface information, seismic soil Shear Strength Loss (SSL) is expected at the site. At locations where SSL triggering may be present, a seismic deformation analysis should be performed to calculate the vertical settlement from the sand-like soil particle re-distribution. In addition, the lateral displacements should also be calculated from lateral spreading of the liquefied soils and their impact on foundations should be addressed.

Following the acquisition of additional subsurface information, the Design-Build Team should carefully evaluate the liquefaction potential at the site and determine if ground improvement is necessary to accommodate seismically induced deformations.

6.3. Static Settlement

In general, the proposed bridge and roadway embankment subgrade soils consist of low density/consistency sandy soils below the static, groundwater table. Fill placement along the project will result in deformation of the subgrade soils. We anticipate that any problematic soils near the ground surface, would be removed and replaced prior to fill placement, since these soils would be difficult to stabilize prior to embankment construction. We anticipate that a majority of the settlement across the project would occur rapidly with fill placement. The potential for extensive, long-term consolidation settlements appears to be low at the site.

6.4. Embankment Slope Stability

Static and seismic embankment slope stability analyses are required at the bridge embankments. Only static stability analyses are required at the roadway embankment locations as defined in the GDM. From reviewing the boring logs, we anticipate that ground improvement and/or modification will be required at the bridge and roadway embankments to generate resistance factors that meet the GDM design criteria.

6.5. Pile Corrosion and Deterioration Potential

Per AASHTO LRFD Bridge Design Specifications, the following soil or site conditions are considered indicative of a potential for steel and/or concrete pile deterioration or corrosion.

1. Resistivity less than 2,000 ohm-cm;
2. pH less than 5.5;
3. pH between 5.5 and 8.5 in soils with high organic content;
4. Sulfate concentrations greater than 1,000 ppm;
5. Landfills and cinder fills;
6. Soils subject to mine or industrial discharge; and,
7. Areas with a mixture of high resistivity soils and low resistivity high alkaline soils.

Corrosion series laboratory testing consisting of pH, resistivity, sulfate content, and chloride content testing was performed on select soils within soil boring B-3 and bulk sample BS-1. The results from the corrosion series laboratory testing are provided in Section 9 of the Appendix. Based on the results from the corrosion series testing, the potential for subsurface steel corrosion or concrete degradation at this site is low. Following additional subsurface testing, the D-B team should carefully evaluate the geotechnical conditions relative to steel corrosion and concrete degradation and provide mitigation measures, as necessary.

6.6. Pile Foundations

Pile foundations are anticipated for support of the bridge. We anticipate that most locations can utilize driven pile techniques. Predrilling or drilled pile techniques may be required to advance the piles below the Santee Limestone caprock. Specific pile foundation design issues are discussed in the following sections.

6.6.1. Axial Resistance

The Strength limit state axial loading conditions will likely govern the geotechnical pile foundation design.

Non-displacement, driven piles will develop a majority of the required driving resistance through a combination of skin friction and tip resistance in the Santee Limestone. The Santee Limestone caprock feature is relatively thin. The Design-Build team should carefully evaluate the structural integrity of this feature before utilizing this layer as a resisting element. We expect that medium to large sized pile hammers will be required to advance the piles through the cemented sand lenses and mobilize the required driving resistance.

Based on the subsurface conditions, displacement piles are suitable at the site. If displacement piles are utilized, we anticipate a composite pile section would be preferred. The composite pile would consist of a larger top of pile section that would develop a majority of the axial resistance and smaller, shorter bottom of pile section that would improve drivability.

We anticipate the pile driving termination criteria will be based on either a wave equation analysis or Pile Dynamic Analyses (PDA) with capacity verification analyses (ie. CAPWAP). If the required driving resistance is not attained during initial drive, then a wait period may be implemented to allow for pile freeze. Following the wait period, pile driving re-strokes should be performed. Continuous PDA testing should be considered during both the initial drive and the re-strokes, if necessary. The number of required PDA tests shall be in accordance with the GDM.

6.6.2. Lateral Resistance

For the Strength limit state, Service limit state, and the Extreme Event limit state, we anticipate that the driven piles will develop the required lateral stability primarily in the Ashley Formation soils and the Santee Limestone soils. The 100-yr and 500-yr scour depths should be implemented in the lateral analyses. The interior bent pile point-of-fixity depths will likely occur below the limestone caprock elevations, and predrilling or drilled pile techniques may be required to advance the piles below the caprock. Seismic SSL should also be evaluated to determine if foundation tip elevations should be extended below the depths needed to satisfy the Strength and Service limit states. At the end bents, the seismic bridge abutment backwall passive pressure shall be calculated in accordance with Chapter 14 of the GDM for the existing embankment fill material or the selected embankment fill material.

6.6.3. Drivability

Driven piles will likely use a diesel pile hammer. We anticipate that non-displacement piles (ie. steel H-piles or steel open-ended pipe piles) will be utilized at the end bents. Pre-stressed concrete (PSC) piles are likely suitable at the interior bents.

Based on the anticipated pile lengths, we expect that most steel pile foundations will require a pile splice and will be driven in two (2) or more sequences. When pile driving in the denser Coastal Plain soils and when pile tip elevations are above the minimum tip elevations, the Contractor should be careful to minimize the time between driving sequences to avoid substantial pile freeze such that the piles cannot be further advanced to the minimum tip elevation requirement.

If PSC piles are utilized, we anticipate that a composite PSC section will be implemented. We anticipate the composite PSC section will include a short steel extension for the primary purposes of improving drivability. The steel section may also be used for lateral stability. Additional pre-stress and/or concrete strength may be required to accommodate hard driving conditions.

We expect that medium to large sized pile hammers will be required to advance the piles through the limestone caprock and beyond the minimum pile tip elevation required for lateral stability. If driving through the caprock is deemed unreliable, then predrilling or drilled pile techniques may be employed to provide a conduit to the underlying medium dense soils. Due to the proximity of residential structures relative to the proposed construction, the Contractor should address earth-borne vibrations in their pile installation plan.

For a properly selected driving system, we do not anticipate unusual pile driving issues for successful installation of the driven piles. The selected driving system shall address driving compressive and tensile stresses to conform to the SC DOT criteria.

6.7. Drilled Shaft Foundations

Drilled shaft foundations are also an option at the site. We anticipate that drilled shaft sizes could range from 36 inch to 48 inch diameter shafts. Specific drilled shaft design issues are discussed in the following sections.

6.7.1. Axial Resistance

The Strength limit state axial loading conditions are expected to govern the geotechnical design of drilled shafts.

Depending on the approach taken by the Design-Build team, we expect that a majority of the drilled shafts will develop the required axial resistance through a combination of skin friction and tip resistance in the Santee Limestone. Since drilled shafts mobilize shaft resistance and tip resistance at different displacements, it is difficult to predict the load transfer from skin resistance to tip resistance. The Design-Build Team should exercise caution when using a drilled shaft design including both skin friction and end bearing in the limestone.

Construction casing is required to facilitate drilled shaft construction. It is anticipated that the casing would be advanced a short distance from the ground surface, and the drilling slurry would provide stability for the excavation below the casing tip elevation. The drilled shaft design methodology does not allow for resistance development in the cased portion of the drilled shaft. As such, the drilled shaft design will generate the required resistance in the uncased portion below the casing tip elevation.

6.7.2. Lateral Resistance

For the Strength limit state and Extreme Event I limit state, the drilled shafts will develop most of the required lateral stability in the limestone. The 100-yr and 500-yr scour depths should be implemented in the lateral analyses. At this site, we expect the axial loading condition will govern the geotechnical drilled shaft design.

6.7.3. Constructability

Drilled shaft construction will likely require excavation of the caprock material and dense, cemented sand lenses (SPT N-values in excess of 100 bpf). The strength of the caprock was not determined during this investigation, but we anticipate that this material is fragile. Regardless, the Design-Build team should include provisions for this material in their drilled shaft installation plan. Specialized drilling equipment not typically used in the Coastal Plain may be required to excavate through the caprock and cemented sands.

As previously discussed, artesian groundwater conditions were observed at the time of our field investigation. The artesian conditions are believed to be contained by the caprock feature at the top of the limestone stratum. For a drilled shaft foundation, we assume that the shafts will penetrate the caprock, and the artesian groundwater may be allowed to move upwards through the annulus of the drilled shaft perimeter and the borehole wall. Artesian conditions can create a variety of design and constructability issues associated with a drilled foundation. The Contractor should address potential artesian groundwater conditions and their impacts on the constructability of the foundations in their drilled shaft installation plan.

6.8. Shallow Foundations

Shallow foundations are not typically utilized on SCDOT bridges due to the difficulty with balancing both settlement and bearing capacity requirements as well as constructability issues. At this site, shallow foundations are not deemed suitable as a bridge substructure element due to the depth required to meet the Strength Limit State and Extreme Event I Limit State bearing capacity and settlement requirements. In addition, the shallow foundation concept would likely require a cofferdam which is an additional prohibitive operation.

7. EXISTING PAVEMENTS AND SUBGRADE SOIL CONDITIONS

Eight (8) asphalt pavement cores were collected from the borings performed along the existing US 15 roadway. In general, the existing pavement section consists of a Hot Mix Asphalt (HMA) section overlying a concrete pavement section. The existing HMA thickness varied from five (5) to fourteen (14) inches, and the concrete pavement thickness varied from approximately seven (7) to eight (8) inches.

CBR testing was performed on material collected in two (2) bulk samples. The quality of the subgrade material near and below the existing pavements is considered “moderate”. A majority of the near surface soil material yielded an AASHTO soil classification of A-2-4 to A-2-7. At bulk sample BS-2 location (offset to soil boring B-2), a CBR value of approximately twenty (20) was recorded. At bulk sample BS-4 location (offset to soil boring R-4), a CBR value of approximately fourteen (14) was recorded.

8. LIMITATIONS OF REPORT

This report has been prepared in accordance with generally accepted geotechnical engineering practice for specific application to the referenced project. The conclusions and recommendations contained herein are based upon the provided test borings and testing result data, contained within, and applicable standards in this geographic area at the time this report was prepared. No other warranty, expressed or implied, is made.

NOTES

1. THE GENERALIZED SUBSURFACE PROFILE IS PROVIDED ONLY FOR ILLUSTRATIVE PURPOSES. THE INTENT OF THIS DRAWING IS TO PROVIDE THE READER WITH VERY GENERAL INFORMATION ON SUBSURFACE CONDITIONS AT THE TIME OF THE INVESTIGATION. VARIATIONS IN THE INDICATED SUBSURFACE CONDITIONS WILL BECOME EVIDENT ONCE ADDITIONAL BORINGS ARE PERFORMED. THE INDICATED STRATIGRAPHY BETWEEN TESTING LOCATIONS WAS GENERATED USING STRAIGHT-LINE LINEAR INTERPOLATION, AND DOES NOT REPRESENT THE TRUE STRATIGRAPHY.

The generalized subsurface profile is provided for illustrative purposes only. The intent of this drawing is to provide the reader with very general information on the subsurface conditions at the site at the time of the investigation. Variations in the indicated subsurface conditions will become evident once additional borings are performed. The indicated stratigraphy between testing locations was generated using straight-line linear interpolation and does not represent the true stratigraphy.

US 15 Bridge Replacement over Indian Field Swamp
Geotechnical Base Line Report

APPENDIX

SECTION 6 CPT LOGS

Cone Penetration Test

CPT-1

Date: Sep. 19, 2019

Estimated Water Depth: 8 ft

Rig/Operator: CME 45-B/L. Guempel

Station: 90+57

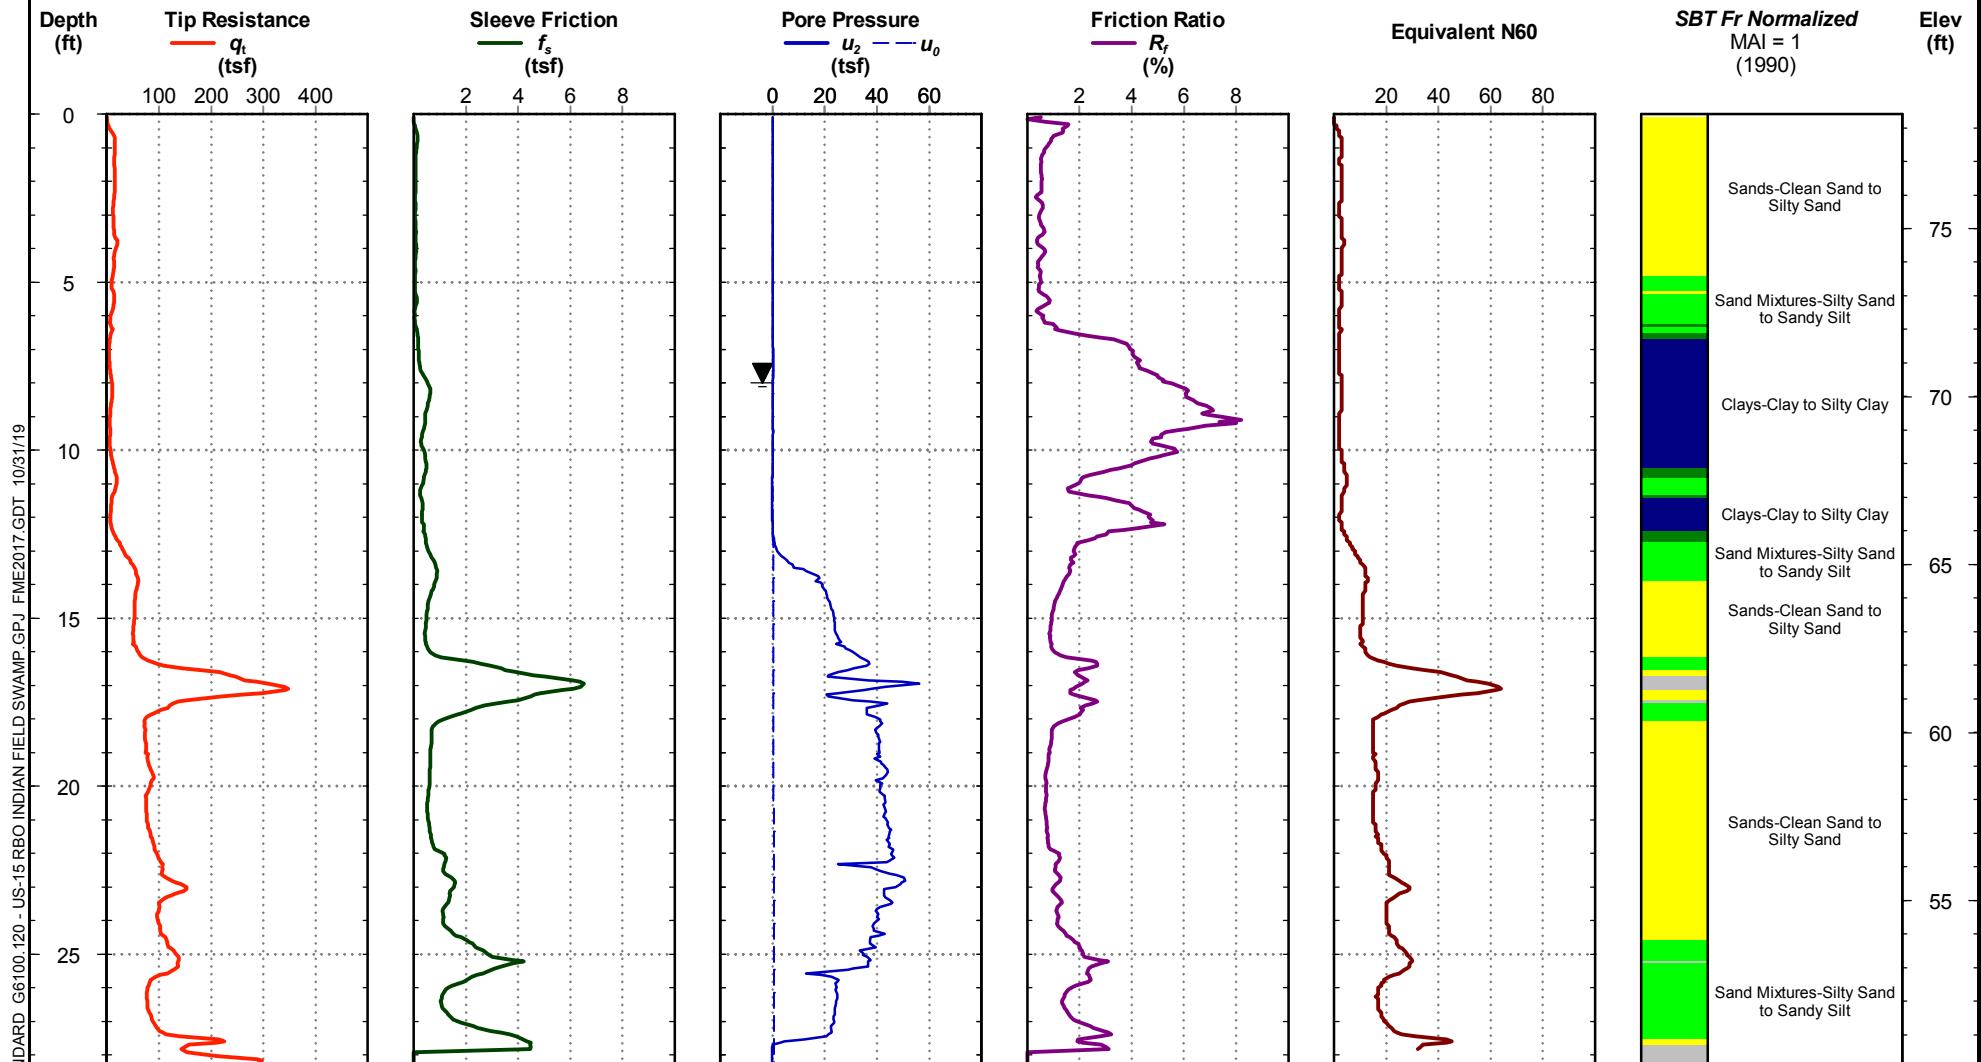

Offset: 13'-LT

Elevation: 78.4

Total Depth: 28.3 ft

Termination Criteria: Maximum Reaction Force

Cone Size:

CPT-1

Cone Penetration Test

CPT-2

Date: Sep. 19, 2019

Estimated Water Depth: 7 ft

Rig/Operator: CME 45-B/L. Guempel

Station: 91+29

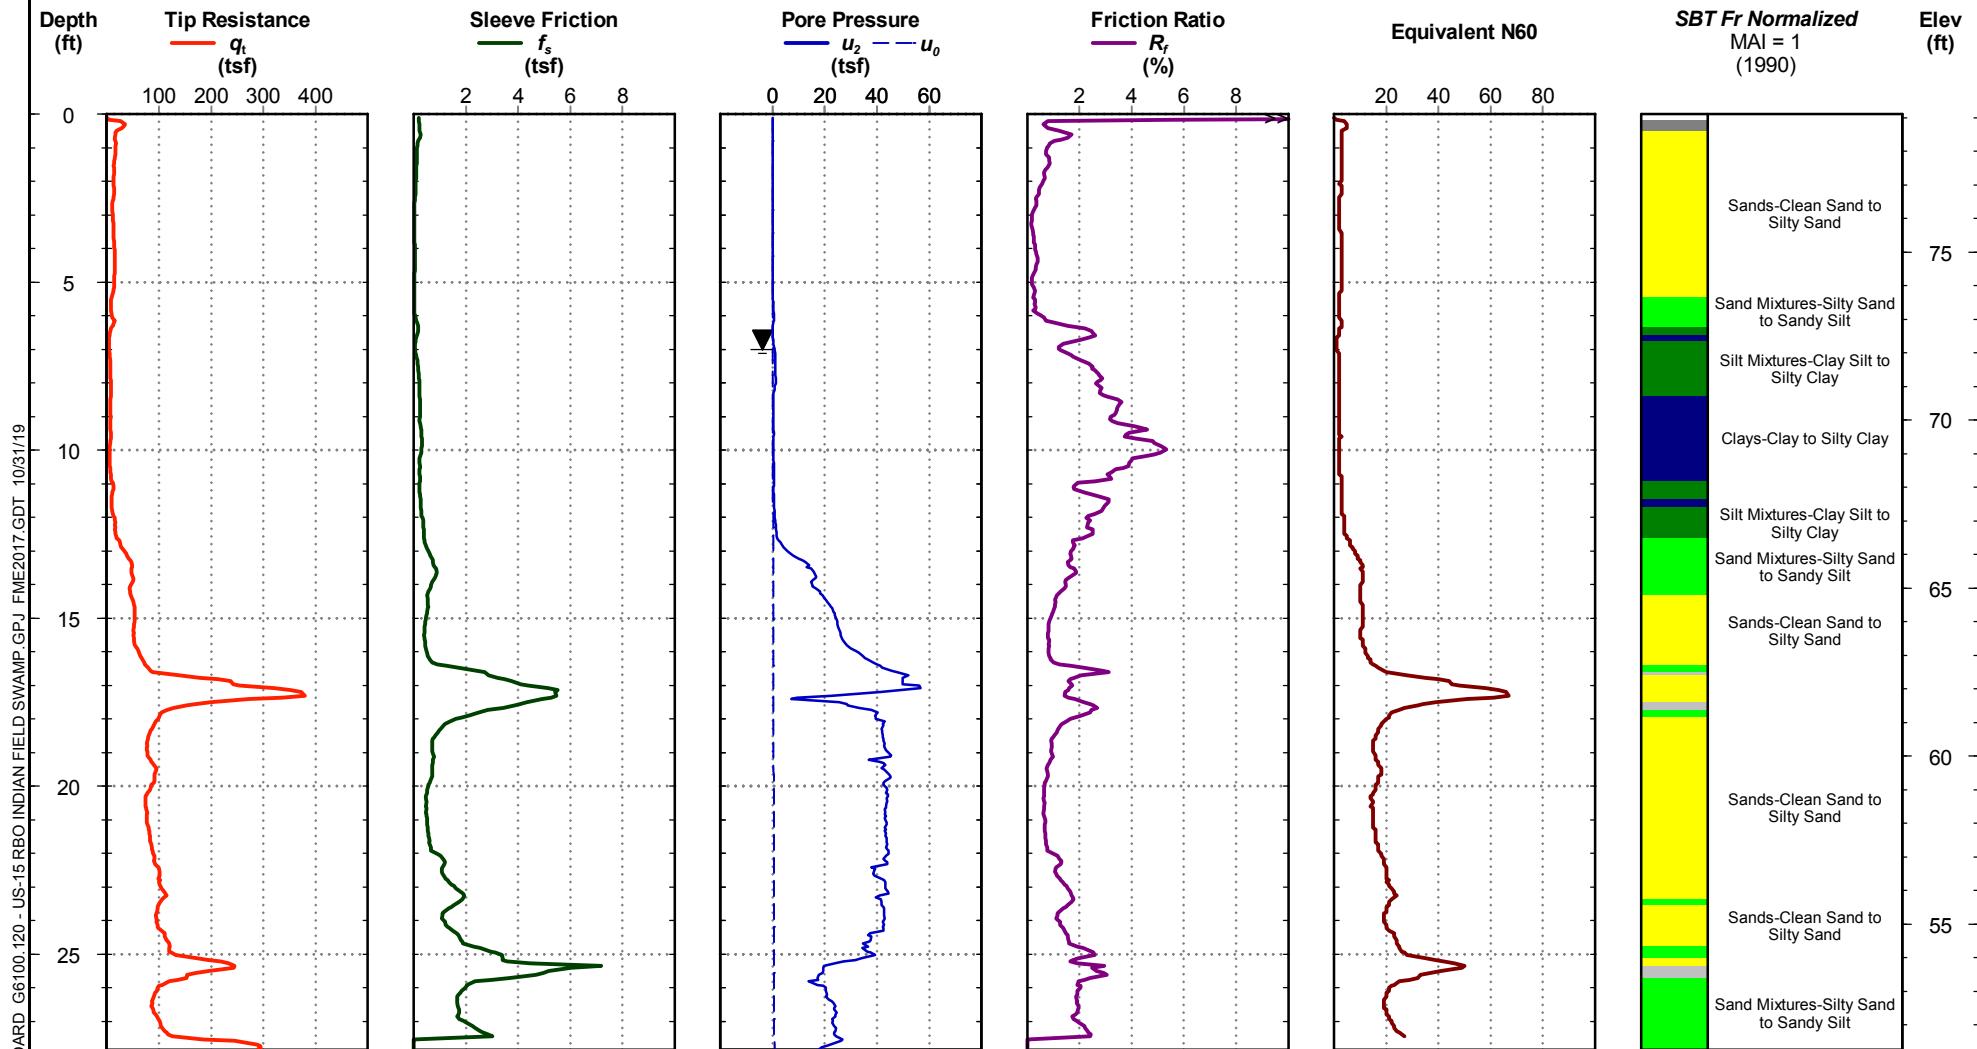

Offset: 13'-RT

Elevation: 79.1

Total Depth: 27.8 ft

Termination Criteria: Maximum Reaction Force

Cone Size:

CPT-2

Cone Penetration Test

CPT-3

Date: Sep. 19, 2019

Station: 97+94

Total Depth: 18.0 ft

Estimated Water Depth: 9 ft

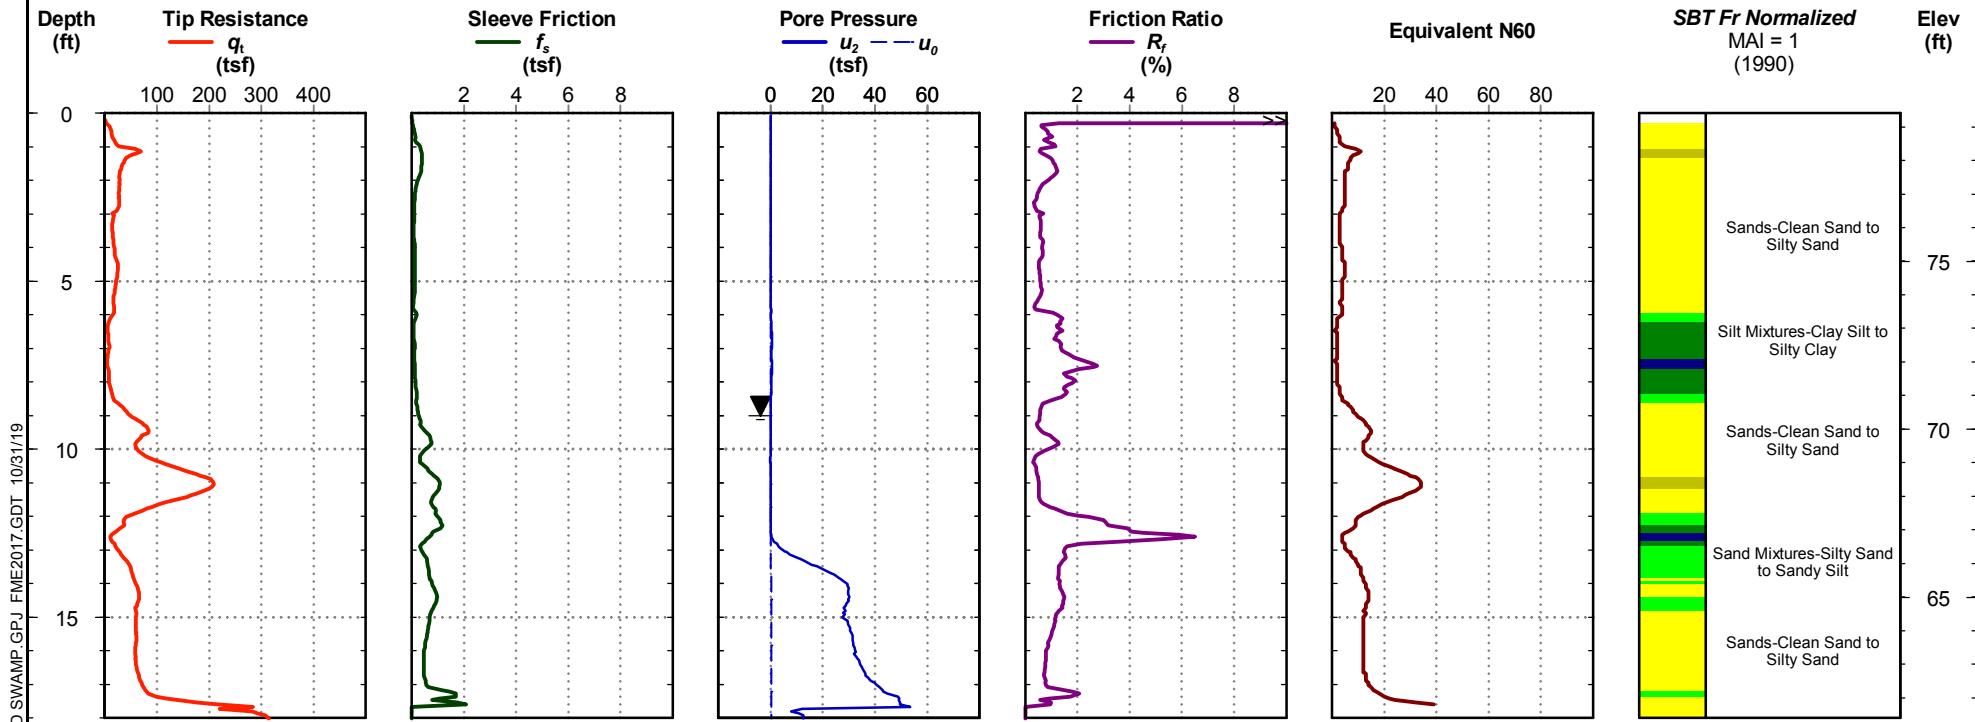

Offset: 12'-LT

Termination Criteria: Maximum Reaction Force

Rig/Operator: CME 45-B/L. Guempel

Elevation: 79.4

Cone Size:

Date: Sep. 19, 2019

Estimated Water Depth: 9 ft

Rig/Operator: CME 45-B/L. Guempel

Station: 97+79

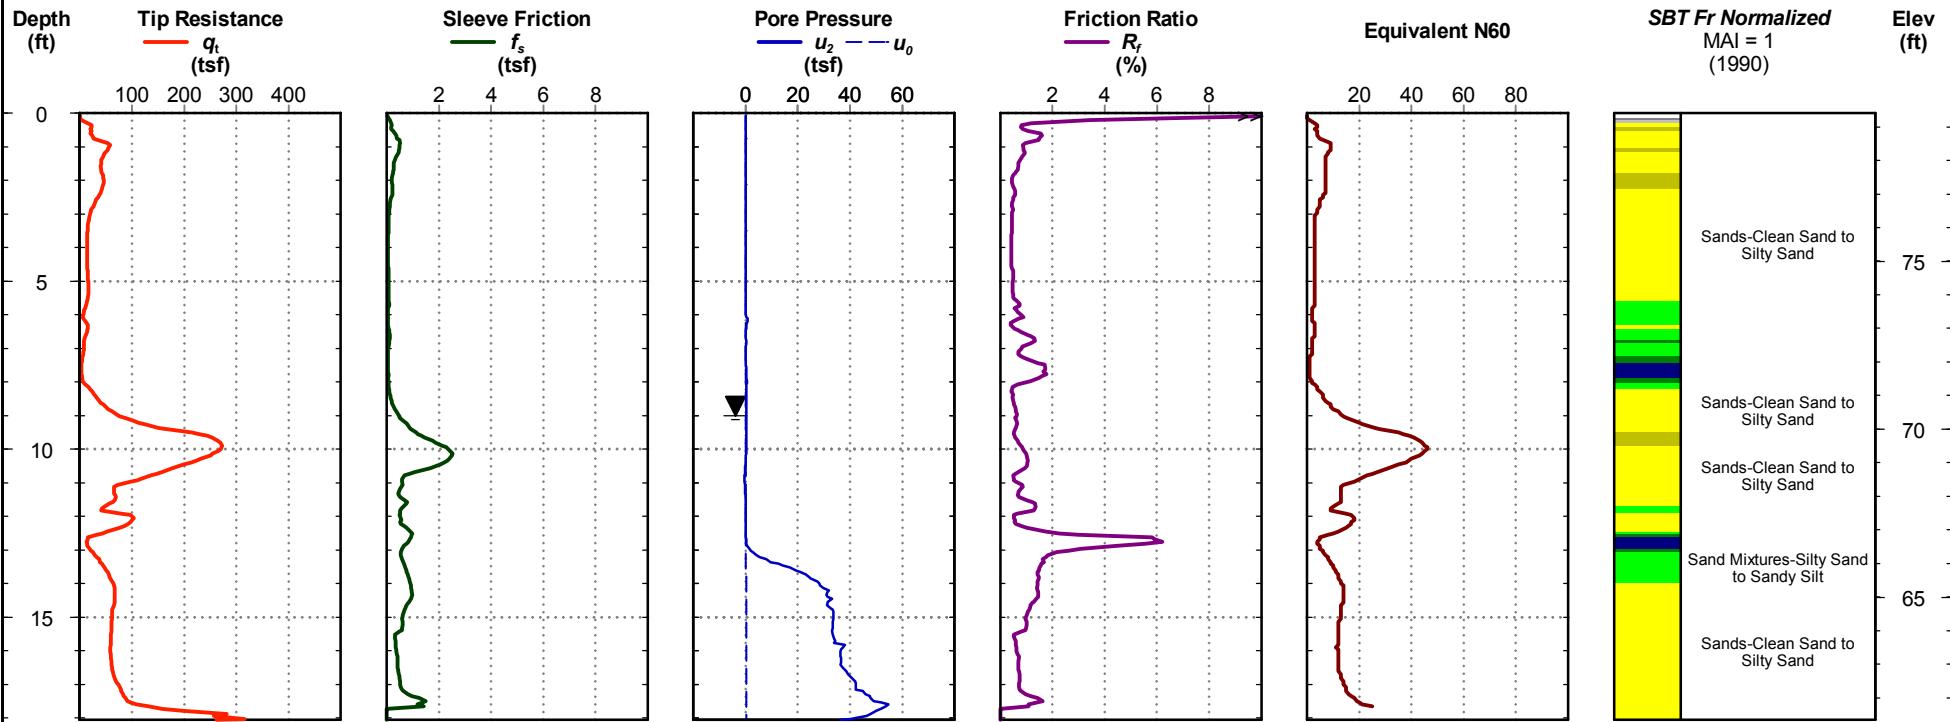

Offset: 12'-LT

Elevation: 79.4

Total Depth: 18.1 ft

Termination Criteria: Maximum Reaction Force

Cone Size:

Cone Penetration Test

CPT-4

Date: Sep. 19, 2019

Station: 98+92

Total Depth: 18.6 ft

Estimated Water Depth: 9 ft

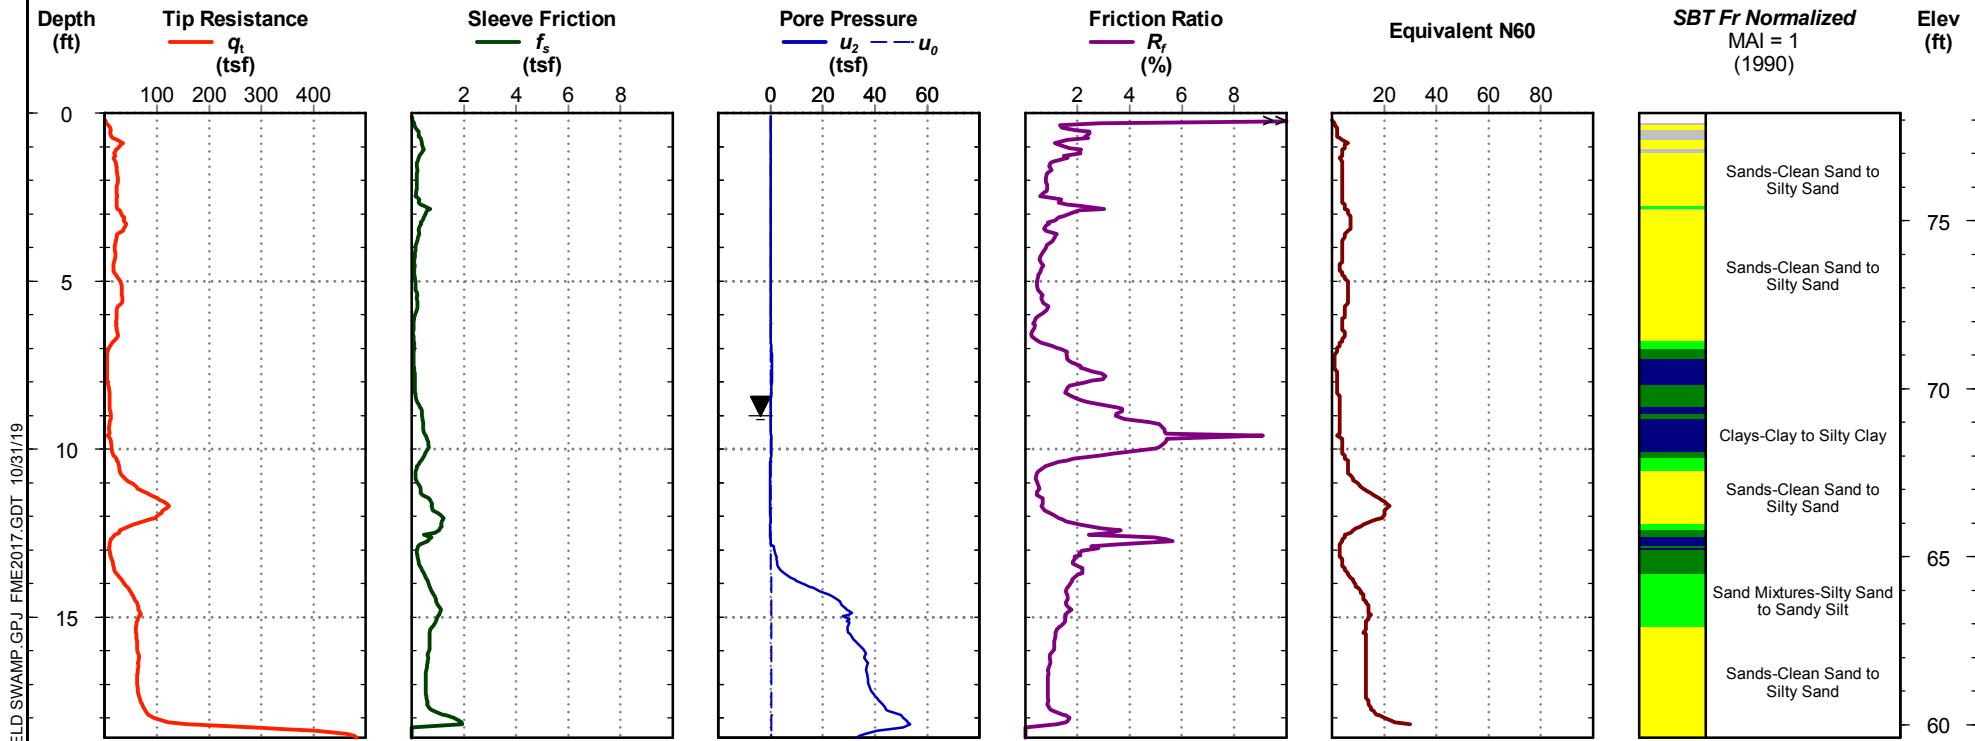

Offset: 14'-RT

Termination Criteria: Maximum Reaction Force

Rig/Operator: CME 45-B/L. Guempel

Elevation: 78.2

Cone Size:

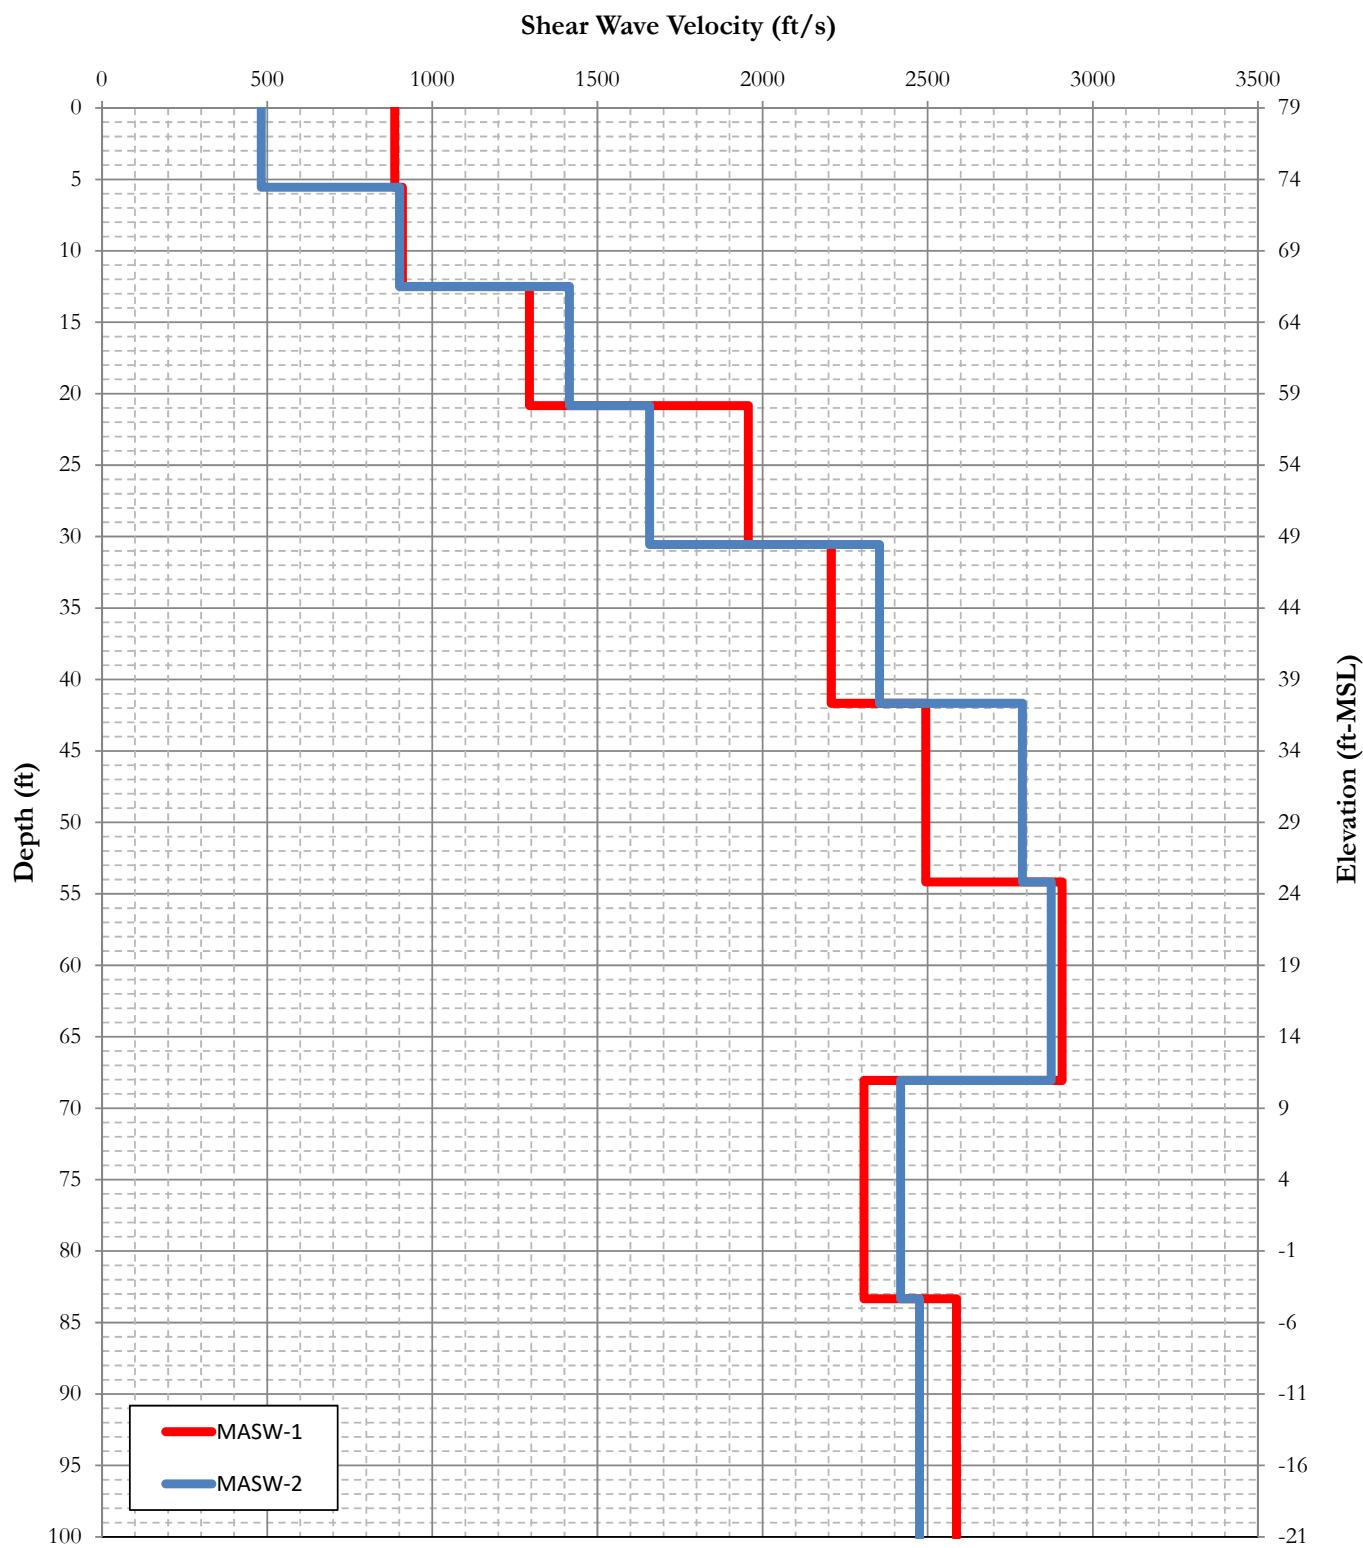

CPT-4

This is to attest that we have examined: Soil for Project Name: US 15 over Indian Field Swamp; Site Location: - ; Job Number: GTX-310810

When examined to the applicable requirements of:

AASHTO T-291-13 "Standard Method of Test for Determining Water-Soluble Chloride Ion Content in Soil" Method B

AASHTO T-290-16 "Standard Method of Test for Determining Water-Soluble Sulfate Ion Content in Soil"

Results:

AASHTO T-291 – Chloride Method B

| Sample | | Results | | Detection Limit |
|--------|--------|-------------|----------------|-----------------|
| | | ppm (mg/kg) | % ¹ | |
| BS-1 | - | <10. | <0.0010 | 10. |
